Variable Arguments & Argument Unpacking

Copyright 2017 Aaron Maxwell - powerfulpython.com

The basics

I'll assume you know how to define functions with default arguments.

```
>>> def foo(a, b, x=3, y=2):
...     return (a+b)/(x+y)
...
>>> foo(5, 0)
1.0
>>> foo(10, 2, y=3)
2.0
>>> foo(b=4, x=3, a=1)
1.0
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Accepting 0 or more arguments

Sometimes you want to define a function that can take any number of arguments. Python's syntax for doing that looks like this:

```
# Note the asterisk. That's the magic part
def takes_any_args(*args):
    print("Type of args: " + str(type(args)))
    print("Value of args: " + str(args))
```

```
>>> takes_any_args(1)
Type of args: <class 'tuple'>
Value of args: (1,)
>>> takes_any_args("x", "y", "z")
Type of args: <class 'tuple'>
Value of args: ('x', 'y', 'z')
>>> takes_any_args()
Type of args: <class 'tuple'>
Value of args: ()
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Stored in tuple

Within the function, `args` is a tuple:

```
def takes_any_args(*args):
    print("Type of args: " + str(type(args)))
    print("Value of args: " + str(args))
```

```
>>> takes_any_args(5, 4, 3, 2, 1)
Type of args: <class 'tuple'>
Value of args: (5, 4, 3, 2, 1)
>>> takes_any_args(["first", "list"], ["another","list"])
Type of args: <class 'tuple'>
Value of args: (['first', 'list'], ['another', 'list'])
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Single Argument vs. *args

```
>>> def takes_any_args(*args):
...     print("Type of args: " + str(type(args)))
...     print("Value of args: " + str(args))
...
>>> def takes_a_list(items):
...     print("Type of items: " + str(type(items)))
...     print("Value of items: " + str(items))
...
>>> data = ["x", "y", "z"]
>>> takes_a_list(data)
Type of items: <class 'list'>
Value of items: ['x', 'y', 'z']
>>> takes_any_args(data)
Type of args: <class 'tuple'>
Value of args: (['x', 'y', 'z'],)
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

*args

By convention, the tuple argument's default name is `args`. But it doesn't have to be.

```
def read_files(*paths):
    data = ""
    for path in paths:
        with open(path) as handle:
            data += handle.read()
    return data

# ch1.txt has text of Chapter 1; ch2.txt for Ch. 2, etc.
story = read_files("ch1.txt", "ch2.txt", "ch3.txt", "ch4.txt")
```

Quick exercise

Open a file named `varargs1.py` and type in the following:

```
def print_args(*args):
    for arg in args:
        print(arg)

print_args("red", "blue", "green")
```

You should see this output, one color per line:

```
red
blue
green
```

Extra credit: Can you find a way to call `print_args`, with different arguments, that triggers an error?

Copyright 2017 Aaron Maxwell - powerfulpython.com

Calling Keyword Arguments

What about keyword arguments?

```
>>> def get_rental_cars(size, doors=4, transmission='automatic'):
...     template = "Looking for a {}-door {} car with {} transmission...."
...     print(template.format(doors, size, transmission))
...
>>> get_rental_cars("economy", transmission='manual')
Looking for a 4-door economy car with manual transmission....
```

In fact, *any* Python function can be called with keyword args:

```
>>> def normal_function(a, b, c):
...     print("a: {} b: {} c: {}".format(a,b,c))
...
>>> normal_function(a=1, b=2, c=3)
a: 1 b: 2 c: 3
>>> normal_function(c=3, b=2, a=1)
a: 1 b: 2 c: 3
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Variable Keyword Arguments

Keyword arguments can't be captured by the `*args` idiom:

```
def print_args(*args):
    for arg in args:
        print(arg)
```

```
>>> print_args(a=4, b=7)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: print_args() got an unexpected keyword argument 'a'
```

What do we do?

Copyright 2017 Aaron Maxwell - powerfulpython.com

kwargs

For keyword arguments, use `**` syntax:

```
def print_kwargs(**kwargs):
    for key, value in kwargs.items():
        print("{} -> {}".format(key, value))
```

`kwargs` is a **dictionary**.

```
>>> print_kwargs(hero="Homer", antihero="Bart", genius="Lisa")
hero -> Homer
genius -> Lisa
antihero -> Bart
```

Notice this is normal Python syntax for calling a function. Has nothing to do with `**kwargs`.

Copyright 2017 Aaron Maxwell - powerfulpython.com

Combine them

Combine them together:

```
def print_all(*args, **kwargs):
    for arg in args:
        print(arg)
    for key, value in kwargs.items():
        print("{} -> {}".format(key, value))
```

A defined function can use either `*args`, or `**kwargs`, or both.

Copyright 2017 Aaron Maxwell - powerfulpython.com

Some notes...

- `args` and `kwargs` are conventional names. Use them unless it's more readable to do something different.
- Always be clear on the types:
  - `args` is a tuple, in the same order as passed in
  - `kwargs` is a dictionary, unordered

Copyright 2017 Aaron Maxwell - powerfulpython.com

Quick exercise

Create a file named `varargs2.py` and type in the following (on the left). When run, it should print the output on the right.

varargs2.py source

```
def print_all(*args, **kwargs):
    for arg in args:
        print(arg)
    for key, value in kwargs.items():
        print("{} -> {}".format(key, value))

print_all("dog", "cat")
print_all(x=7, z=3)
print_all("red", "green", x=7, z=3)
```

program output

```
dog
cat
z -> 3
x -> 7
red
green
z -> 3
x -> 7
```

EXTRA CREDIT: How can you write a function taking from 0 to 4 arguments (but no more)? How about 0 to 20? What are the different approaches and trade-offs?

Copyright 2017 Aaron Maxwell - powerfulpython.com

Positional + kwargs

```
def add_to_dict(stuff, **kwargs):
    for key, value in kwargs.items():
        # Do not overwrite existing values.
        if key not in stuff:
            stuff[key] = value
    return stuff
```

```
>>> add_to_dict({})
{}
>>> add_to_dict({}, foo=42)
{'foo': 42}
>>> add_to_dict({"foo": 42}, bar=21)
{'bar': 21, 'foo': 42}
>>> add_to_dict({"foo": 42}, foo=21)
{'foo': 42}
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Another problem

Suppose library A defines this function:

```
def order_book(title, author, isbn):
    """
    Place an order for a book.
    """
    print("Ordering '{}' by {} ({})".format(title, author, isbn))
    # ...
```

... and library B defines this one:

```
def get_required_textbook(class_id):
    """
    Returns a tuple (title, author, ISBN)
    """
    # ...
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Incompatible types

These don't quite match, so we have to glue them together.

```
>>> title, author, isbn = get_required_textbook(4242)
>>> order_book(title, author, isbn)
Ordering 'Writing Great Code' by Randall Hyde (1593270038)
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Incompatible types

Alternatively you could do this, which is pretty horrible:

```
>>> book_info = get_required_textbook(4242)
>>> order_book(book_info[0], book_info[1], book_info[2])
Ordering 'Writing Great Code' by Randall Hyde (1593270038)
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Tedious and Error-Prone

Python provides a better way.

```
>>> def normal_function(a, b, c):
...     print("a: {} b: {} c: {}".format(a,b,c))
...
>>> numbers = (7, 5, 3)
>>> normal_function(*numbers)
a: 7 b: 5 c: 3
>>> # Exactly equivalent to:
... normal_function(numbers[0], numbers[1], numbers[2])
a: 7 b: 5 c: 3
```

Notice `normal_function` is just a regular function! This is called **argument unpacking**.

Copyright 2017 Aaron Maxwell - powerfulpython.com

Argument unpacking

Given these:

```
one_args = [ 42 ]
two_args = (7, 10)
three_args = [1, 2, 3]

def f(n): return n / 2
def g(a, b): return a + b
def h(x, y, z): return x * y * z
```

The following pairs are all equivalent:

```
f(one_args[0])
f(*one_args)

g(two_args[0], two_args[1])
g(*two_args)

h(three_args[0], three_args[1], three_args[2])
h(*three_args)
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Back to the books...

So instead of this....

```
>>> book_info = get_required_textbook(4242)
>>> order_book(book_info[0], book_info[1], book_info[2])
Ordering 'Writing Great Code' by Randall Hyde (1593270038)
```

We can do this:

```
>>> book_info = get_required_textbook(4242)
>>> order_book(*book_info)
Ordering 'Writing Great Code' by Randall Hyde (1593270038)
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Keyword Unpacking

Just like with `*args`, double-star works the other way too. We can take a regular function, and pass it a dictionary using two asterisks:

```
>>> def normal_function(a, b, c):
...     print("a: {} b: {} c: {}".format(a,b,c))
...
>>> numbers = {"a": 7, "b": 5, "c": 3}
>>> normal_function(**numbers)
a: 7 b: 5 c: 3
>>> # Exactly equivalent to:
... normal_function(a=numbers["a"], b=numbers["b"], c=numbers["c"])
a: 7 b: 5 c: 3
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Matching Keys

Keys of the dictionary *must* match up with how the function was declared:

```
>>> bad_numbers = {"a": 7, "b": 5, "z": 3}
>>> normal_function(**bad_numbers)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: normal_function() got an unexpected keyword argument 'z'
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Calling both

You can call a function using both - and both will be unpacked:

```
>>> def addup(a, b, c=1, d=2, e=3):
...     return a + b + c + d + e
...
>>> nums = (3, 4)
>>> extras = {"d": 5, "e": 2}
>>> addup(*nums, **extras)
15
```

Copyright 2017 Aaron Maxwell - powerfulpython.com

Two different things

Python uses `*args` and `**kwargs` for two *very different* things:

- Variable arguments (when *defining* a function), and
- Variable unpacking (when *calling* a function).

These look similar in code. **But they are completely different things.**
